IPv4 and IPv6 Integration

Formation IPv6
Workshop Location, Date
Agenda

Introduction

Approaches to deploying IPv6
- Standalone (IPv6-only) or alongside IPv4
- Phased deployment plans

Considerations for IPv4 and IPv6 coexistence

Approaches to coexistence
- 1: Dual-Stack
- 2: Tunnelling
- 3: Translation

Specific examples
- 6to4 and Tunnel broker, ISATAP
- NAT-PT, Application Layer Gateways (ALGs)
Introduction

Terminology
Transition/Migration vs Integration/Coexistence
- One suggests a change from one protocol to another
- The other suggests a graceful introduction where both protocols exist together for a period of time
- The peaceful coexistence of IPv4 and IPv6 is a must

IPv6 Deployment Today
- Implies ‘legacy’ IPv4 will be present
- Applications may choose which protocol to use

IPv6 Perspective
- IPv6 protocols can be added to and are inherently extensible
- It is thus generally easier to consider integration from the IPv6 perspective
IPv6 only?

When deploying IPv6, you have two choices:

- Deploy IPv6-only networking
- Deploy IPv6 alongside IPv4

Currently IPv6 is not mature in certain commercial application and management products, though support on host OS and router platforms is very good

- This will influence current decisions towards dual-stack (use IPv6 where available, else IPv4)
- This situation is continuously improving over time
Deploy IPv6 standalone

Typically IPv6 will be deployed today dual-stack
But one option is to deploy an IPv6-only network
This introduces specific requirements:

- All components (network, OS, apps) must be IPv6-capable
- Likely to need to talk to legacy IPv4-only systems
  - Need a way to ‘translate’ between the protocols at some layer
- Likely to want to communicate with remote IPv6 network ‘islands’ that may only be connected through existing IPv4 networks
  - Need a way to send IPv6 packets over/through an intermediate IPv4-only network
- IPv6-only deployments are rare today, but will come
Deploy IPv6 alongside IPv4

Existing network runs IPv4

(Incrementally) introduce IPv6 to the same network, deploying IPv6 in parallel to IPv4
• Known as ‘dual-stack’ operation
• Hosts and routers are able to talk using either protocol

Choice of protocol is application-specific
• DNS returns IPv4 and IPv6 addresses for a given hostname
• As an example, MS Internet Explorer by default prefers IPv6 connectivity, but can fall back to IPv4 (after a timeout)
• Thus need to be confident IPv6 connectivity is good, else the application may perform worse than in an IPv4-only network
Phased IPv6 deployment

Each site or network will need to form its own plan for IPv6 deployment

Need to consider various factors, e.g:

• Technical
  ▪ Do we need upgrades? Applications?
• Policy
  ▪ How do we handle (manage and monitor) IPv6 traffic?
• Education
  ▪ Are our support people trained to operate IPv6?

Then schedule the process
Phase 1: advanced planning

Phase 1 includes:

• Add IPv6 capability requirements to future tenders
  ▪ Ensure you have capability to deploy
• Obtain IPv6 address space from your ISP/NREN (LIR) or from your RIR if you’re a ISP
  ▪ Typically a /48 size prefix (from the LIR)
  ▪ And a /32 size prefix (from the RIR)
• Arrange IPv6 training
• Encourage in-house experiments by systems staff
  ▪ e.g. using Tunnel Broker services
• Review IPv6 security issues
  ▪ IPv6 is often enabled by default - your users may be using IPv6 without your knowledge...
Phase 2: Testbed/Trials

Phase 2 includes:

- Deploy IPv6 capable router, with cautious ACLs applied
- Establish connectivity (probably a tunnel) to your ISP
- Set up an internal link with host(s), on a /64
  - Can be isolated from regular IPv4 network (e.g. a dual-stack DMZ running IPv4 and IPv6 together)
- Enable IPv6 on the host systems, add DNS entries if appropriate

And in parallel

- Survey systems and applications for IPv6 capabilities
- Formulate an IPv6 site addressing plan
- Document IPv6 policies (e.g. address assignment methods)
Phase 3: Production rollout

Prudent to enable IPv6 on the wire first, then services

Phase 3 includes:
- Plan initial deployment areas, e.g. your existing IPv4 DMZ or WLAN may be good first steps
- Enable external IPv6 connectivity and ACLs/filters
- Enable IPv6 routing ‘on the wire’ on selected internal links
- Deploy IPv6 support in management/monitoring tools

Then enable the services and advertise via DNS:
- Enable IPv6 in selected services (e.g. web, SMTP)
- Add IPv6 addresses to DNS, enable IPv6 DNS transport

Remember IPv6 security:
- e.g. include IPv6 transport in all penetration tests
Various transition approaches

1: Dual Stack
   - Servers/devices speaking both protocols

2: Tunnels ("connecting the IPv6 islands")
   - IPv6 encapsulated over IPv4 links
   - IPv6 packet is payload of IPv4 packet
   - Requires "open" holes in firewalls
     ▪ Packets whose Protocol field is '41'

3: Translation methods ("IPv4-only to IPv6-only")
   - Rewriting IP header information
   - TCP relay devices
   - Application layer gateways (ALGs)
1: Dual-stack

Support both protocols on selected links (and nodes)

Requires support in:
- Host platforms
- Router platforms
- Applications and services
  - e.g. web, DNS, SMTP

Adds considerations for
- Security in all components
- New policies dependent on IPv6-specific features

Can run global IPv6 alongside NAT-ed IPv4
Dual-stack issues

Application must choose which IP protocol to use

- DNS returns IPv4 (A record) and IPv6 addresses (AAAA record)
- e.g. MS Internet Explorer prefers IPv6
- Don’t advertise AAAA record for a host unless you have good IPv6 connectivity (for all services on host)

Enabling IPv6 should not adversely impact IPv4 performance

- Consider whether IPv6 tunnels use router CPU for example

Security should be no worse

- Hosts listen on both protocols; secure both
Aside: IPv4 mapped addresses

An IPv6 address used to represent an IPv4 address

A socket API may receive an IPv4 connection as an IPv6 address, known as an IPv4-mapped address

• Format is ::ffff:<ipv4-address>
• e.g. ::ffff:152.78.64.1

NB: This is one socket for both address families

Should not be seen ‘on the wire’, i.e. not as source or destination address

May appear in log files, depending on how the application handles a connection

Typically seen in dual-stack deployments
2: Tunnelling

Initially IPv6 in IPv4, (much) later IPv4 in IPv6
So, IPv6 packets are encapsulated in IPv4 packets
  • IPv6 packet is payload of IPv4 packet

Usually used between edge routers to connect IPv6 ‘islands’
  • Edge router talks IPv6 to internal systems
  • Encapsulates IPv6 in IPv4 towards remote tunnel endpoint
Packet delivery over the tunnel

IPv6 node A sends packet to IPv6 node B
  • Routed internally to edge router A

Edge router A sees destination network B is reachable over tunnel interface
  • Encapsulates IPv6 packet in IPv4 packet(s)
  • Sends resulting IPv4 packet(s) to edge router B
  • Delivered over existing IPv4 Internet infrastructure

Edge router B decapsulates IPv6 packet from payload of received IPv4 packet
  • Packet routed internally in network B to node B
  • Node B receives the IPv6 packet
Tunnel addressing view

IPv6 node A
2001:db8:1::1
IPv6 Network
2001:db8:1::/48

IPv4 src: 152.78.1.1
IPv4 dst: 1.20.100.1
IPv6 src: 2001:db8:1::1
IPv6 dst: 2001:db8:2::1

IPv6 node B
2001:db8:2::1
IPv6 Network
2001:db8:2::/48

Router IPv4 interface 152.78.1.1
Dual stack router
IPv4 network
Router IPv4 interface 1.20.100.1
Dual stack router
Fragmentation

IPv6 requires that packet fragmentation only occurs at end systems, not on intermediate routers
  • Use Path Maximum Transmission Unit (PMTU) Discovery to choose the MTU
  • Achieved using special ICMP messages
  • Minimum MTU is 1280 bytes in IPv6

When tunnelling IPv6 in IPv4, the IPv4 packets may be fragmented
  • Depends on the IPv4 packet size
  • Additional IPv6 headers (e.g. Authentication Header) will affect this
Tunnel solution considerations

These include:

• Security
• Manual or automatic setup
• Ease of management
• Handling dynamic IPv4 addresses
• Support for hosts or sites to be connected
• Scalability: 10, 100, or 10,000 served tunnels?
• Support for NAT traversal
• Tunnel service discovery
• Support for special services (e.g. multicast)
• Tunnel concentration/bandwidth usage issues

We’ll come back to these later...
Manual or automatic?

Can create tunnels manually or automatically

Manual tunnels

- Requires manual configuration, at both ends
  - Usually just one command/config line in the router at each end
  - Agreement on addresses to use for interfaces
- Good from a management perspective: you know who your tunnels are created with

Automatic tunnelling

- Tunnels created on demand without manual intervention
- Includes 6to4 (RFC3056)
  - Quite popular in SOHO deployments
- Also: ISATAP and Teredo

Marrakech -Formation IPv6 -Avril 2009
Configured tunnels

Very easy to setup and configure

Good management potential

- ISP configures all tunnels, so is in control of its deployment
- This is the current approach used by many NRENs (including UKERNA and RENATER) to connect academic sites/users over IPv6 where native IPv6 connectivity is not available

Usually used router-to-router or host-to-router

- Desirable to allow end user to register (and subsequently authenticate) to request a tunnel
- The IPv6 Tunnel Broker (RFC3053) offers such a system, usually for host-to-router connectivity, but sometimes for router-to-router.
Tunnel broker

Very popular in IPv6 user community
Most well-known broker is www.freenet6.net
  • Hosted in Canada by Hexago

General mode of operation is:
  • User/client registers with the broker system
  • A tunnel is requested from a certain IPv4 address
  • The broker sets up its end of the requested tunnel on its tunnel server
  • The broker communicates the tunnel settings to the user, for client-side configuration

Can traverse a NAT, e.g. if UDP tunnelling used
Broker: systems view

1. User connects to Tunnel Broker web interface requesting tunnel
2. TB returns script to create tunnel to the Tunnel Server, and informs TS of new client
3. Client executes script, and gains access to IPv6 networks via the TS
Broker: Logical view

1: Client requests tunnel and (in some cases) authenticates
2: Broker sends remote endpoint configuration to tunnel server
3: Broker returns configuration to client system to create tunnel
4: Tunnel established
Broker issues

Broker’s key advantage is its manageability
- ISP can track usage levels

A few downsides:
- If broker is topologically remote, round trip times for data may suffer
  - e.g. using freenet6 in Canada to reach UK sites
- Not well-suited if IPv4 address is dynamic
  - Common problem in home DSL networks
- Client tool required to operate through a NAT
- If using a remote tunnel broker, your own ISP may not perceive a demand for IPv6
Automatic tunnelling

Goal is to avoid requiring support staff effort to setup and maintain tunnels
Set up required tunnels on demand
Make deployment and usage simple(r) for the end user
Most common automatic method is 6to4 (RFC3056)
  • Generally used router-to-router
  • Well supported in commercial routing platforms
Other methods include ISATAP (RFC4214) and Teredo
  • We don’t cover Teredo (RFC4380) in this slideset; it is a NAT-traversing IPv6 connectivity method used by Microsoft in XP/Vista.
3: Translation

When an IPv4-only system needs to communicate with an IPv6-only system, translation is required.

Can be done at various layers:

Network layer
- Rewrite IP headers

Transport layer
- Use a TCP relay

Application layer
- Use an application layer gateway (ALG)

Ideally avoid translation
- Use IPv4 to speak to IPv4 systems and IPv6 for IPv6 systems.
Translation scenarios

Generally when deploying IPv6-only network elements and you need them to communicate with IPv4-only systems

- Legacy applications that cannot be ported to support IPv6
  - Or perhaps source code not available
- Legacy IPv4-only operating systems
  - For example Windows 98
- Legacy IPv4-only hardware
  - Printers
Network layer: NAT-PT

Network Address Translation - Protocol Translation
• Defined in RFC2766
• Like IPv4 NAT, but with protocol translation

Uses Stateless IP/ICMP Translation (SIIT)
• Defined in RFC2765
• SIIT defines algorithms to translate between the IPv4 and IPv6 header fields, where it’s possible

NAT-PT extends SIIT with IPv4 address pools
• IPv4-to-IPv6 and IPv6-to-IPv4 supported
NAT-PT topology

Src: IPv6 address
Dst: <IPv6-prefix>:<IPv4-address>
NAT-PT and DNS

Internal network IPv6 only
DNS ALG watches for IPv6 (AAAA) DNS queries, and translates to IPv4 (A) queries
When IPv4 DNS response comes back, DNS ALG maps the result to an IPv6 address
- <IPv6-prefix>:<IPv4 address>
- A special NAT-PT IPv6 prefix is taken from the IPv6 network’s address space

Querying host now uses an IPv6 destination that NAT-PT maps to real IPv4 destination
NAT-PT downsides

Has all shortcomings of IPv4 NAT, and more
- IP addresses may be embedded in payload (e.g. FTP)
- DNS considerations are complex

Can use from IPv4 network into IPv6 network
- If enough IPv4 global addresses available to advertise special NAT-PT prefix addresses externally

It’s considered a ‘last resort’ mechanism
- NAT-PT has been deprecated ‘historical’ within the IETF (see RFC4966 for details)
Application: ALGs

NAT-PT and TRT are somewhat complex

Luckily, application layer gateways (ALGs) offer a simpler alternative

Many applications support ALGs already
  • Web cache
  • SMTP gateway
  • DNS resolver
  • SIP proxy
  • etc

We can leverage this in a simple way
ALG topology

[Diagram showing the relationship between IPv6 only network, IPv4 web servers, IPv6 web servers, and a dual-stack web cache.]
ALG pros and cons

Pros

• Simple to deploy
• ALGs already commonly in use, e.g.
  ▪ Web cache to reduce bandwidth usage
  ▪ SMTP relay to channel mail through one server
• Avoids complexity of NAT-PT or TRT

Cons

• Requires client configuration to use ALG
• Only works for specific ALG-supported applications - not suited for peer-to-peer apps
But what’s the best method?

We have a “toolbox” of IPv6 transition methods
Some suited to certain scenarios
IPv4 hosts will be around for a long time, with
transition ongoing for many years (10-20+ years)
Usage depends on scenario

- A university may run dual-stack internally, and use a manual
tunnel to their NREN until a native connection is available
- A home user with IPv6 enabled on his laptop may use a tunnel
broker to gain IPv6 connectivity to their home
- Alternatively, a SOHO environment may be suited to 6to4
  - Especially where a static IPv4 address is available

There is no single ‘best’ solution
Finally: perspectives

Potentially deployed by a (campus) site:

• Dual-stack networking
• Manual tunnels
• ALGs
• 6to4 router (for small, typically SOHO, sites)
• NAT-PT (for IPv6-only subnets without ALG capability)

Potentially offered/supported by an ISP:

• Tunnel broker server
• Manual tunnels
• 6to4 relay
Conclusions

There is a large set of IPv6 transition tools available
  • No single ‘best’ solution
  • Transition plan is likely to be site-specific

Current ‘best practice’ is dual-stack deployment
  • Natural path via procurement cycles
  • Allows experience in IPv6 operation to be gained early

IPv6-only networks can be deployed
  • But very limited in number to date, and missing some apps

Ultimate driver is IPv4 address space availability
  • But also need IPv4 addresses for a smooth transition
Questions ...
